Some introduction.

your name

#### Bayesian theory

#### Building blocks

- Prior probability  $p(\theta)$
- Likelihood  $p(\mathcal{D}|\theta)$

Posterior probability

$$p(\theta|\mathcal{D}) = \frac{p(\mathcal{D}|\theta)p(\theta)}{\int p(\mathcal{D}|\theta')p(\theta')d\theta'}$$

#### Bayesian theory

**Building blocks** 

- Prior probability  $p(\theta)$
- Likelihood  $p(\mathcal{D}|\theta)$

Posterior probability

$$p(\theta|\mathcal{D}) = \frac{p(\mathcal{D}|\theta)p(\theta)}{\int p(\mathcal{D}|\theta')p(\theta')d\theta'}$$

Using posterior probability:

$$\int_{\Theta} f(\theta) p(\theta|\mathcal{D}, M) d\theta$$

#### Bayesian theory

**Building blocks** 

- Prior probability  $p(\theta)$
- Likelihood  $p(\mathcal{D}|\theta)$

Posterior probability

$$p(\theta|\mathcal{D}) = \frac{p(\mathcal{D}|\theta)p(\theta)}{\int p(\mathcal{D}|\theta')p(\theta')d\theta'}$$

Using posterior probability:

$$\int_{\Theta} f(\theta) p(\theta|\mathcal{D}, M) d\theta$$

Bayesian theory requires integration!

#### Approximate inference

Ways to integrate:

Monte Carlo

$$\int_{\Theta} f(\theta) p(\theta|\mathcal{D}) d\theta \approx \frac{1}{N} \sum_{i=1}^{N} f(\theta_i), \ \theta_i \sim p(\theta|\mathcal{D})$$

Approximate distribution

$$p(\theta|\mathcal{D}) pprox q(\theta), \quad \int_{\Theta} f(\theta)q(\theta)d\theta$$

#### Approximate inference

Ways to integrate:

Monte Carlo

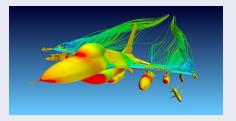

$$\int_{\Theta} f(\theta) p(\theta|\mathcal{D}) d\theta \approx \frac{1}{N} \sum_{i=1}^{N} f(\theta_i), \ \theta_i \sim p(\theta|\mathcal{D})$$

Approximate distribution

$$p(\theta|\mathcal{D}) pprox q(\theta), \quad \int_{\Theta} f(\theta)q(\theta)d\theta$$

Usual methods demands many evaluations of  $p(\mathcal{D}|\theta)p(\theta)$ . However, this is not always feasible.

In science, there are many cases that  $p(\mathcal{D}|\theta)$  demands the computation of a forward model  $g(\theta)$ , which comes from an expensive simulation.

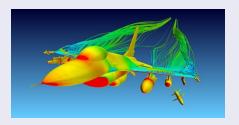

In science, there are many cases that  $p(\mathcal{D}|\theta)$  demands the computation of a forward model  $g(\theta)$ , which comes from an expensive simulation.

This requires approximate inference methods "on a budget". In this work, one such method is developed, based on preexisting work. We name it

#### Definition

Gaussian processes (GP): distribution over functions  $f: \mathcal{X} \to \mathbb{R}$  such that  $f(\mathbf{x}) = (f(x_1), \dots, f(x_n))$  follows a multivariate normal distribution. A GP is completely defined by:

- $m(x) := \mathbb{E}[f(x)]$ , mean function.
- $k(x, x') := \mathbb{E}[f(x), f(x')]$ , covariance function or kernel.

such that  $f(\mathbf{x}) \sim \mathcal{N}(m(\mathbf{x}), K(\mathbf{x}, \mathbf{x}))$ .

your name The title

#### Definition

Gaussian processes (GP): distribution over functions  $f: \mathcal{X} \to \mathbb{R}$  such that  $f(\mathbf{x}) = (f(x_1), \dots, f(x_n))$  follows a multivariate normal distribution. A GP is completely defined by:

- $m(x) := \mathbb{E}[f(x)]$ , mean function.
- $k(x, x') := \mathbb{E}[f(x), f(x')]$ , covariance function or kernel.

such that  $f(\mathbf{x}) \sim \mathcal{N}(m(\mathbf{x}), K(\mathbf{x}, \mathbf{x}))$ .

#### Gaussian process regression

Given  $\mathcal{D} = (x, y)_{i=1}^N$ , a Gaussian process regression is made by assuming p(y|x) = p(y|f(x)), with f following a prior GP(m, k).

#### Posterior GP

If 
$$p(y|f(x)) = \mathcal{N}(f(x), \sigma_n^2)$$
,  $f|\mathcal{D} \sim GP(m_{\mathcal{D}}, k_{\mathcal{D}})$ , where

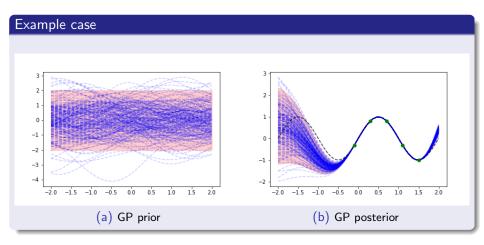

$$m_{\mathcal{D}}(\mathbf{x}) := m(\mathbf{x}) + K(\mathbf{x}^{\star}, \mathbf{x})(K(\mathbf{x}, \mathbf{x}) + \sigma_n^2)^{-1}(\mathbf{y} - m(\mathbf{x}))$$

$$m_{\mathcal{D}}(\mathbf{x}, \mathbf{y}') := k(\mathbf{x}, \mathbf{y}') - K(\mathbf{y}, \mathbf{y})(K(\mathbf{x}, \mathbf{x}) + \sigma_n^2)^{-1}K(\mathbf{y}, \mathbf{y})$$

$$k_{\mathcal{D}}(x,x') := k(x,x') - K(x,\mathbf{x})(K(\mathbf{x},\mathbf{x}) + \sigma_n^2)^{-1}K(\mathbf{x},x)$$

Reduces to deterministic measurement when  $\sigma_n^2 = 0$ . More general p(y|f(x)) must resort to explicit marginalization.

#### Kernels

The exigence that  $K(\mathbf{x}, \mathbf{x})$  limits which functions can be kernels. Some examples of kernels in  $\mathbb{R}$  are:

• 
$$k_{SQE}(x, x') = \theta_0 \exp\left(-\frac{1}{2} \frac{(x - x')^2}{l^2}\right)$$

• 
$$k_{\text{Matern},3/2}(x,x') = \theta_0 \left(\sqrt{3} \frac{(x-x')}{l}\right) \exp\left(-\sqrt{3} \frac{(x-x')}{l}\right)$$

Kernels in  $\mathbb{R}^D$  can be constructed by changing  $\frac{(x-x')}{l}$  for  $\sqrt{\sum_{i=1}^D \frac{(x_i-x_i')}{l_i}}$ . If  $k_1, k_2$  are kernels, the following, among others are kernels:  $k_1(x, x') + k_2(x, x'), k_1(x, x')k_2(x, x'), k_1(x, x')k_2(y, y'), k_1(f(y), f(y'))$ .

4□ > 4□ > 4 = > 4 = > = 90

#### Kernels

The exigence that  $K(\mathbf{x}, \mathbf{x})$  limits which functions can be kernels. Some examples of kernels in  $\mathbb{R}$  are:

• 
$$k_{SQE}(x, x') = \theta_0 \exp\left(-\frac{1}{2} \frac{(x-x')^2}{l^2}\right)$$

• 
$$k_{\text{Matern},3/2}(x,x') = \theta_0 \left(\sqrt{3} \frac{(x-x')}{l}\right) \exp\left(-\sqrt{3} \frac{(x-x')}{l}\right)$$

Kernels in  $\mathbb{R}^D$  can be constructed by changing  $\frac{(x-x')}{l}$  for  $\sqrt{\sum_{i=1}^D \frac{(x_i-x_i')}{l_i}}$ . If  $k_1, k_2$  are kernels, the following, among others are kernels:  $k_1(x,x') + k_2(x,x'), k_1(x,x')k_2(x,x'), k_1(x,x')k_2(y,y'), k_1(f(y),f(y'))$ .

#### Mean functions

In general, they are less important than kernels, since the latter determines the structure of the posterior GP. However, *outside the sampling area the GP prediction defaults to the mean*, which may be of importance.

#### Handling hyperparameters

$$\log p(\mathcal{D}|M, \sigma_n) = -\frac{1}{2}(\mathbf{y} - m(\mathbf{x}))^T (K(\mathbf{x}, \mathbf{x}) + \sigma_n \mathbf{I})^{-1}(\mathbf{y} - m(\mathbf{x})) + \frac{1}{2} \log \det(K(\mathbf{x}, \mathbf{x}) + \sigma_n \mathbf{I}) - \frac{1}{2} N \log(2\pi).$$

Inference can be done either by MLE, MAP, or integration techniques.

#### Scaling

The bottleneck of GP regression:  $(K(\mathbf{x}, \mathbf{x}) + \sigma_n \mathbf{I})^{-1}$ . Cost is  $\mathcal{O}(N^3)$ . In online learning, each new sample is incorporated in  $\mathcal{O}(N^2)$ .

#### Bayesian Monte Carlo

#### Integrating a GP

$$Z = \int f(x)p(x)dx$$

If  $f \sim GP(m, k)$ , given  $\mathcal{D} = \{(x_i, f(x_i))\}_{i=1}^N$ ,  $Z_{\mathcal{D}} = \int f_{\mathcal{D}}(x)p(x)dx$  is Gaussian:

$$\mathbb{E}[Z_{\mathcal{D}}] = \int m(x)p(x)dx - \mathbf{z}^{T}K^{-1}(\mathbf{f} - m(\mathbf{x})), \quad \operatorname{Var}[Z_{\mathcal{D}}] = \Gamma - \mathbf{z}^{T}K^{-1}\mathbf{z},$$

$$z_{i} = \int k(x, x_{i})p(x)dx, \quad \Gamma = \int \int k(x, x')p(x)p(x')dxdx'.$$

#### Bayesian Monte Carlo

#### Integrating a GP

$$Z = \int f(x)p(x)dx$$

If  $f \sim GP(m, k)$ , given  $\mathcal{D} = \{(x_i, f(x_i))\}_{i=1}^N$ ,  $Z_{\mathcal{D}} = \int f_{\mathcal{D}}(x)p(x)dx$  is Gaussian:

$$\mathbb{E}[Z_{\mathcal{D}}] = \int m(x)p(x)dx - \mathbf{z}^{T}K^{-1}(\mathbf{f} - m(\mathbf{x})), \quad \operatorname{Var}[Z_{\mathcal{D}}] = \Gamma - \mathbf{z}^{T}K^{-1}\mathbf{z},$$

$$z_{i} = \int k(x, x_{i})p(x)dx, \quad \Gamma = \int \int k(x, x')p(x)p(x')dxdx'.$$

Name Bayesian Monte Carlo is misleading.

# Bayesian Monte Carlo

### Integrating a GP

$$Z = \int f(x)p(x)dx$$

If  $f \sim GP(m, k)$ , given  $\mathcal{D} = \{(x_i, f(x_i))\}_{i=1}^N$ ,  $Z_{\mathcal{D}} = \int f_{\mathcal{D}}(x)p(x)dx$  is Gaussian:

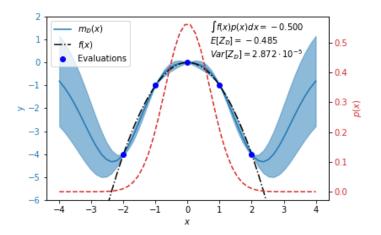

$$\mathbb{E}[Z_{\mathcal{D}}] = \int m(x)p(x)dx - \mathbf{z}^{T}K^{-1}(\mathbf{f} - m(\mathbf{x})), \quad \operatorname{Var}[Z_{\mathcal{D}}] = \Gamma - \mathbf{z}^{T}K^{-1}\mathbf{z},$$

$$z_{i} = \int k(x, x_{i})p(x)dx, \quad \Gamma = \int \int k(x, x')p(x)p(x')dxdx'.$$

Name Bayesian *Monte Carlo* is misleading. Treating f as a random variable may be philosophically odd.

# Bayesian Monte Carlo

# Bayesian Monte Carlo

#### Kernel integral terms

In the general case, they can be estimated by Monte Carlo. When p(x) is Gaussian or a mixture of Gaussians:

- Analytically tractable when k(x, x') is the SQE kernel.
- Efficiently tractable when  $k(x, x') = k(x_1, y_1) \dots k(x_D, y_D)$ .

### Active sampling

Given  $\{(x_1, f(x_1), \dots, x_N, f(x_N))\}$ ,  $x_{N+1}$  may be chosen by optimizing acquisition functions.

$$\alpha_{\mathsf{MMLT}}^{\mathsf{N}}(x) = e^{2m_{\mathcal{D}}(x) + k_{\mathcal{D}}(x,x)} \left( e^{k_{\mathcal{D}}(x,x)} - 1 \right).$$

## Back to approximating posteriors $p(\theta|\mathcal{D}) pprox q(\theta;\lambda)$

Variational Inference: given  $g(\theta)$ , seeks minimization of  $D_{KL}(q(\cdot; \lambda)||g)$ . Given unnormalized  $\bar{g}$ , this is equivalent to maximizing the evidence lower bound (ELBO)

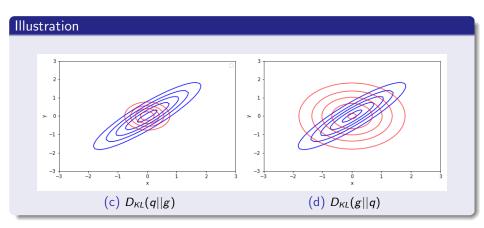

$$\mathcal{L}(\lambda) = \int \log \bar{g}(\theta) q(\theta) d\theta - \int \log q(\theta) q(\theta) d\theta$$

The family of variational posteriors  $q(\theta; \lambda)$  must be easy to treat, in order for the approximation to be useful.

## $D_{\mathit{KL}}(q(\cdot;\lambda)||g)$ vs $D_{\mathit{KL}}(g||q(\cdot;\lambda))$

 $D_{KL}(q(\cdot;\lambda)||g) \neq D_{KL}(g||q(\cdot;\lambda))$ : two minimization objectives. Gives two different algorithms (the second one, *expectation propagation*, is not treated here).

your name The title 17 de outubro de 2019 18 / 31

#### Mean field variational inference

Consider factorized proposals  $q(\theta) = q(\theta_1) \dots q(\theta_D)$ .

Training by coordinate descent

$$q_j^*( heta_j;q_{-j}) \propto \exp \mathbb{E}_{ heta_{-j} \sim q_{-j}}[\log ar{g}( heta)].$$

#### Generic variational inference

Uses stochastic gradient descent to find  $q(\theta; \lambda)$ .

REINFORCE: 
$$\nabla \mathcal{L}(\lambda) = \mathbb{E}_{q(\theta;\lambda)} \left[ \left( \log \left( \frac{\bar{g}(\theta)}{q(\theta;\lambda)} \right) + C \right) \nabla_{\lambda} \log q(\theta;\lambda) \right]$$

Reparametrization:

$$\nabla \mathcal{L}(\lambda) = \nabla \left( \mathbb{E}_{r(\epsilon)} \left[ \log \frac{\bar{g}(s(\epsilon;\lambda))}{q(s(\epsilon;\lambda);\lambda)} \right] \right) \approx \frac{1}{K} \sum_{i \in [K], \epsilon_i \sim r(\epsilon)} \nabla \left( \log \frac{\bar{g}(s(\epsilon;\lambda))}{q(s(\epsilon;\lambda);\lambda)} \right).$$

#### Mixture of Gaussians

 $q_k(\theta; \lambda) = \sum_{i=1}^k w_i f_i(\theta) = \sum_{i=1}^k w_i \mathcal{N}(\theta; \mu, \Sigma_i)$ . Analytical mean and covariance. Samples can be easily generated.

Covariance parameterizations:

• 
$$\Sigma_i = \operatorname{diag}(\sigma_{i,1}^2, \ldots, \sigma_{i,D}^2)$$

• 
$$\Sigma_i = \mathbf{u}_i \mathbf{u}_i^T + \operatorname{diag}(\sigma_{i,1}^2, \dots, \sigma_{i,D}^2)$$

Weights parameterizations  $w_i(\nu_i) = \frac{\phi(\nu_i)}{\sum_{i=1}^k \phi(\nu_i)}$ .  $\phi$  can be:

• 
$$\phi(\nu) = \exp(\nu)$$

• 
$$\phi(\nu) = \operatorname{softplus}(\nu) = \log(1 + \exp(\nu))$$

$$\mathcal{L}(\lambda) = \sum_{i=1}^{k} w_i(\nu_i) \mathbb{E}_{\epsilon \sim \mathcal{N}(0, l)} \left[ \log \frac{\bar{g}(s(\epsilon; \mu_i, \sigma_i))}{q_k(s(\epsilon; \mu_i, \sigma_i); \lambda)} \right]$$

#### Boosting mixtures

Problem: no way to know how many mixtures is needed. Adding mixtures sequentially can become costly. One solution: boosting.

$$\begin{aligned} q_{i-1}(\theta) &= \sum_{j=1}^{i-1} w_j f_j(\theta) \\ q_i(\theta) &= \sum_{j=1}^{i-1} (1 - w_i) w_j f_j(\theta) + w_i f_i(\theta) \\ \text{How to find } w_i \text{ and } f_i(\theta) &= \mathcal{N}(\theta; \mu_i, \Sigma_i)? \end{aligned}$$

- Optimize jointly  $\mathcal{L}_i(w_i, \mu_i, \Sigma_i)$
- Seek good proposal  $f_i(\theta)$  and optimize  $\mathcal{L}_i(w_i)$  via it's derivative

$$\mathcal{L}_i'(w_i) = \int \log(ar{g}( heta))(f_i( heta) - q_{i-1}( heta))d heta - \ \int \log((1-w_i)q_{i-1}( heta) + w_if_i( heta))(f_i( heta) - q_{i-1}( heta))d heta.$$

#### Gradient boosting of mixtures

$$f_i = \operatorname*{arg\,min}_f 
abla D_{\mathit{KL}}(q_{i-1}||g) \cdot f = \operatorname*{arg\,min}_f \int \log rac{q_{i-1}( heta)}{g( heta)} f( heta) d heta.$$

Problem: degenerate solution. Needs regularization.

Maximization objective for mixture of Gaussians:

$$\begin{split} \mathsf{RELBO}(\mu_i, \Sigma_i) &= \int \mathsf{log}(\bar{g}(\theta)) \mathcal{N}(\theta | \mu_i, \Sigma_i) d\theta - \\ & \int \mathsf{log}(q_{i-1}(\theta)) \mathcal{N}(\theta | \mu_i, \Sigma_i) d\theta + \frac{\lambda}{4} \mathsf{log} \, |\Sigma|, \end{split}$$

Estimated by the reparameterization trick.

```
1: procedure VariationalBoosting(log \bar{g}, \mu_0,\Sigma_0)

```

## Variational Bayesian Monte Carlo (VBMC)

$$\mathcal{L}(\lambda) = \int \log \bar{g}(\theta) q(\theta; \lambda) d\theta - \int \log q(\theta; \lambda) q(\theta; \lambda) d\theta$$
  
Use Bayesian Monte Carlo:

$$\mathcal{L}_{\mathcal{D}}(\lambda) = \int \log \bar{g}_{\mathcal{D}}(\theta) q(\theta; \lambda) d\theta - \int \log q(\theta; \lambda) q(\theta; \lambda) d\theta$$

Maximize 
$$\mathbb{E}[\mathcal{L}_{\mathcal{D}}(\lambda)] = M(\lambda) + \mathbf{z}^T \mathbf{w} - \int \log q(\theta; \lambda) q(\theta; \lambda) d\theta$$

$$\mathbf{w} = K^{-1} \mathbf{y}$$

$$M(\lambda) = \int m(\theta) q(\theta; \lambda) d\theta$$

$$\mathbf{z}_i = \int k(x, x_i) q(\theta; \lambda) dx.$$

#### Mean function

 $m(\theta) = 0$ :  $\log \bar{g}_{\mathcal{D}}(\theta)$  is not a log probability

Principled solution:  $m(\theta) = -\frac{1}{2} \sum_{i=1}^{D} \frac{(\theta_i - c_i)^2}{l_i^2}$ . Lends analytical  $M(\lambda)$ .

Ad-hoc solution:  $m(\theta) = C$ , with C being a large negative constant.

#### Active evaluation

Just as in BMC, it is possible to do active evaluation. Some options:

- $\alpha_{\text{US}}^{\mathcal{D}}(\theta_{N+1}) = k_{\mathcal{D}}(\theta_{N+1}, \theta_{N+1}) q_k(\theta_{N+1}; \lambda)^2$ .
- $\alpha_{\text{PROP}}^{\mathcal{D}}(\theta_{N+1}) = k_{\mathcal{D}}(\theta_{N+1}, \theta_{N+1}) \exp(m_{\mathcal{D}}(\theta_{N+1})) q_k(\theta_{N+1}; \lambda)^2$

26/31

# Boosted Variational Bayesian Monte Carlo

#### **BVBMC**

BVBMC = VBMC + boosting + small changes

#### BMC in boosted variational inference

$$\begin{split} \mathsf{RELBO}_{\mathcal{D}}(\mu_i, \Sigma_i) &= \int \mathbb{E}[\log \bar{g}_{\mathcal{D}}(\theta)] \mathcal{N}(\theta | \mu_i, \Sigma_i) d\theta - \\ & \int \log(q_{i-1}(\theta)) \mathcal{N}(\theta | \mu_i, \Sigma_i) d\theta + \frac{\lambda}{4} \log |\Sigma_i| \end{split}$$

$$egin{aligned} \mathcal{L}_{i,\mathcal{D}}(w) &= \int \log ar{g}_{\mathcal{D}}( heta)((1-w_i)q_{i-1}( heta) + w_if_i( heta))d heta - \ &\int \log((1-w_i)q_{i-1}( heta) + w_if_i( heta))((1-w_i)q_{i-1}( heta) + w_if_i( heta))d heta \end{aligned}$$

# Boosted Variational Bayesian Monte Carlo

#### Practical considerations

RELBO stabilization

$$\mathsf{RELBO}_{\mathcal{D}}^{\delta_D}(\mu_i, \Sigma_i) = \int \log \left( \frac{r_{\mathcal{D}}(\theta)}{q_{i-1}(\theta) + \delta_D} \right) \mathcal{N}(\theta; \mu_i, \Sigma_i) d\theta + \log |\Sigma_i|.$$

Output scaling

$$\tilde{y}_i = (y_i - m_y)/\sigma_y, \, \tilde{\mathcal{D}} = \{x_i, \tilde{y}_i\}, \, \sigma_y \log g_{\tilde{\mathcal{D}}}(x) + \mu_y$$

- Component pruning: discard negligible components
- Initialization: either large covariance or maximize ELBO for first Gaussian component.
- Mean function:  $m(\theta) = C$  found to be more stable.

#### Practical considerations

- Periodic joint parameter updating: sometimes maximize  $\mathbb{E}[\mathcal{L}_{\mathcal{D}}(\lambda)]$  for all parameters in  $\sum_{i=1}^{k} w_k \mathcal{N}(\theta; \mu_k, \Sigma_k)$ .
- Product of Matern kernels:

$$k_{\mathsf{PMat},\nu}(x,x';\theta,I) = \theta \prod_{d=1}^{D} k_{\mathsf{Matern},\nu}(|x_i - x_i'|;I_d).$$

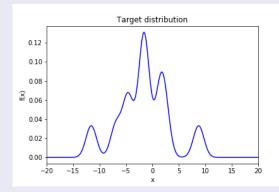

Is integrated in BVBMC by Gauss-Hermite quadrature. Found to be more stable than the SQE kernel.

• More acquisition functions:

$$\alpha_{MMLT}^{\mathcal{D}}(x_{m+1}) = e^{2m_{\mathcal{D}}(x) + k_{\mathcal{D}}(x,x)} \left( e^{k_{\mathcal{D}}(x,x')} - 1 \right).$$

$$\alpha_{MMLT_P}^{\mathcal{D}}(x_{m+1}) = e^{2m_{\mathcal{D}}(x) + k_{\mathcal{D}}(x,x)} \left( e^{k_{\mathcal{D}}(x,x')} - 1 \right) q_k(\theta_{N+1};\lambda)^2.$$

#### 1-d mixture of Gaussians

$$f(x) = \sum_{i=1}^{12} w_i \mathcal{N}(x; \mu_i, \sigma_i^2),$$

$$w_i = \frac{1}{12}$$
,  $\mu_i \sim \mathcal{N}(0, \sqrt{5})$ ,  $\sigma_i^2 = 1$ .
